

Assignment 2

Arrays & Procedural routines

Design Specs:

The module implements a simple combinational processor that performs one of four operations on an 8-bit input data word based on a 2-bit operation select input.

Port Name	Port Type	Width	Description
data_in	Input	8 bits	Input data word to be processed.
op_sel	Input	2 bits	Operation select signal to choose the required operation.
data_out	Output	8 bits	Result of the selected operation applied to data_in.

Output changes immediately based on operation type and inputs according to the following table:

op_sel	Operation	Output Result
2'b00	Increment	data_out = data_in + 1
2'b01	Decrement	data_out = data_in - 1
2'b10	Bitwise NOT	data_out = ~data_in
2'b11	Left Shift	data_out = data_in << 1
default	Pass-through	data_out = data_in

Objective:

We need test the **multi_op_processor** combinational DUT using proper data types and routines,

- Declare Dynamic array of proper datatype (Choose the most appropriate one in your opinion and mention why you chose it) to store the stimulus for the design.
- Queue to Collect the output values from the design.
- Associative array holds the expected values from the golden model and storing them with index type int (the index represents the stimulus number).

- Declare the following tasks or functions with the following specs:

- **configure_stim_storage (int size)**: This function will be used to configure the size of the dynamic array that holds the stimulus with the size *u* passed to the function. And always clear the content of the actual data queue and expected data associative array after allocating a new size to guarantee the right data being stored in these storages with each re-configuration for the size.
- **generate_stimulus (<dynamic array (as reference)>)**: To randomize the stimulus and save it in the dynamic array storage.
- **drive_stim ()**: Task which iterates through previously prepared stimulus with the dynamic array and send the stimulus to DUT.
- **golden_model (<Associative Array as reference>)**: This task takes the stimulus you sent to design and calculate the expected results then store it in the associative array to be used afterward with checks.
- **collect_output_data (<data from design outputs>)**: To collect the data have been read from the design and store it with the queue.
- **check_results (<Expected data>, <Actual data>)**: Takes the expected data stored in the Associative array previously prepared in golden model **and** the actual output data from the design stored in the queue **and** iterates through them and makes the checks with proper display statements to indicates whether the data is successful as expected or not.
- **reconfigure_stim (<dynamic array>)**: To just make randomization on the order of the stimulus stored previously in the dynamic array using the appropriate array sorting method (what will *u* choose?). **Note** after using this function you will need to update the expected values order and re calculate it again based on the new order.

Helpful Steps:

The expected flow you will walk through is to

1. Configure the stimulus storage size with **100 locations** for the stimulus.
2. Prepare the stimulus by generating them and store them (expected to be 100).
3. Driving the stimulus to the design.
4. Sending the stimulus generated to the golden model to calculate the expected data and store them.
5. Collecting the data from the design after some delay 1ns and gathering them into the meant storage for output date from the design as mentioned above.
6. Making the checks on the collected stored actual data from design comparing with the expected stored date from the golden model.
7. Repeat the above steps after re-configuring the dynamic array size with **200 locations**.
8. Then make some re-ordering on the stimulus storage you have and repeat the testing process again of re-calculating the golden model, driving the stimulus and making the checks again.

Use the tasks and functions described above to perform all the steps mentioned to automate the process

Deliverables:

U have to deliver

- **Zip Folder** contains:
 - The implemented **.sv** files and the **design files** and **run.do** file.
- **Separated PDF** contains:
 - Snippets for the implemented code.
 - Snippet for the waveform shows the values for created variables
 - Snippets for the logs show the all printed values.
 - Snippet for Do file you have used for automating the process.

The delivered zip file must be named like **your_name_Assignment_1.rar** for example:
Hassan_Khaled_Assignment_1.rar also the PDF file **Hassan_Khaled_Assignment_1.pdf**

Deadline:

The deadline is Thu 17/7 at 6 PM

Good Luck
